# Finite MDP with Reachability

- A system with finitely many states (finite underlying graph)
- 2 types of states: random and controlled
- Objective: reach/avoid a subset  $F$  of states
- Deciding the following is in PTIME
  - “ $\exists$  strategy:  $\mathcal{P}(\text{reach } F) \geq \rho$ ?” (reachability, MAX)
  - “ $\exists$  strategy:  $\mathcal{P}(\text{reach } F) \leq \rho$ ?” (safety, MIN)

# Pros and Cons of Finite MDP

Pros: Well studied model; low complexity of model-checking

Cons: Infinite space often required:

- Recursive procedures
- Unbounded counting

# Extending the Finite MDP

Requirement: finite representability

- Finite Automaton  $\rightarrow$  Pushdown Automaton
  - Natural model for recursive processes
  - Transition graph of PDA is infinite
  - **Cons:** Undecidability for very basic questions
- Finite Automaton  $\rightarrow$  One-Counter Automaton
  - Interesting model from multiple points of view
  - Transition graph of OC is infinite
  - **Cons:** Weaker than PDA
  - **Pros:** Interesting questions decidable

# Extending with Counter

## Motivation:

- A natural restriction of PDA – unary stack alphabet
- Enhancing the finite automaton inside MDP with a counter
- (Adversarial extension of) a discrete time Quasi Birth-Death Process, a model of a queue
- OC-MDP subsume *solvency games* [Berger et al., 2008]

# OC-MDP in Pictures

# OC-MDP in Pictures

## OC-MDP in Detail

- Game graph: vertices =  $s(n)$  (state and counter value)
- Objectives – 2 kinds of termination
  - non-selective = reaching  $s(0)$  in **any** state  $s$
  - selective = reaching  $s(0)$  for  $s \in F$ , a specified subset of states
- Reachability is equivalent to selective termination

  - One-Counter Automata
  - **Solvency Games**
- 2 Problems
  - Questions
  - Long Run Properties
  - Non-selective Termination
  - Selective Termination
  - Solvency Games
- 3 Future Work

# Solvency Games

- Initial pot of money
- Finite # of wealth-changing distributions
- Repeated choices of the distributions
- Goal: avoid bankrupt (**not** maximise profit)

Only **red** changes counter

  - Solvency Games
- 3 Future Work

## Interesting Questions

Is there a strategy for the OC-MDP so that the probability of the following events satisfies e.g.  $= 1$ ,  $> 0$ ,  $\geq \rho \dots$ ?

- The stack is erased and any state, or a particular one is reached
- The queue represented by the QBD gets eventually empty
- The gambler is going bankrupt
- The value of the counter gets less than every bound
- ...

# Accumulated Reward

Maximize  $\mathcal{P}(\{\liminf_{n \rightarrow \infty} (\text{counter value at } n\text{-th step}) = -\infty\})$

- Optimal strategies always **exist**, are **deterministic** and **only** need to know the **state** (not history, nor counter value)
- Finding an optimal strategy is in polynomial time

Minimize  $\mathcal{P}(\{\liminf_{n \rightarrow \infty} (\text{counter value at } n\text{-th step}) = -\infty\})$ ?

## Accumulated Reward

- Optimal strategies always **exist**, are **deterministic** and **only** need to know the **state** (not history, nor counter value)
- Finding an optimal strategy is in polynomial time

Maximize  $\mathcal{P}(\{\limsup_{n \rightarrow \infty} (\text{counter value at } n\text{-th step}) = -\infty\})$ ?

# Strategy Synthesis I.

How to find a strategy for maximizing

$$\mathcal{V} := \mathcal{P}(\{\liminf_{n \rightarrow \infty}(\text{counter at step } n) = -\infty\})?$$

It suffices to define it on vertices with  $\mathcal{V} = 1$

- The rest is reaching these vertices
- The proof exploits the simple form of optimal strategies – plugging them in yields a finite Markov Chain

## Strategy Synthesis II.

How to find a strategy for

$$\mathcal{P} \left( \left\{ \liminf_{n \rightarrow \infty} (\text{counter at step } n) = -\infty \right\} \right) = 1?$$

It is reducible to finding a strategy for

$$\mathcal{P} \left( \left\{ \lim_{n \rightarrow \infty} \left( \frac{\text{counter at step } n}{n} \right) \leq 0 \right\} \right) = 1$$

## Strategy Synthesis II.

How to find a strategy for

$$\mathcal{P} \left( \left\{ \liminf_{n \rightarrow \infty} (\text{counter at step } n) = -\infty \right\} \right) = 1?$$

It is reducible to finding a strategy for

## Non-selective Termination

- If  $\mathcal{V} := \sup_{\sigma} \mathcal{P}^{\sigma}(\bullet) = 1$  then there is an **optimal** strategy  $\sigma$  which is **deterministic** and **only** needs to know the **state** (not history, nor counter value)
- This strategy can be computed in polynomial time

## Non-selective Termination

- If  $\mathcal{V} := \sup_{\sigma} \mathcal{P}^{\sigma}(\bullet) = 1$  then there is an **optimal** strategy  $\sigma$  which is **deterministic** and **only** needs to know the **state** (not history, nor counter value)
- This strategy can be computed in polynomial time

# Selective Termination

- Even if  $\mathcal{V} := \sup_{\sigma} \mathcal{P}^{\sigma}(\bullet) = 1$  then there may not be an optimal strategy  $\sigma$
- If there is then there is a **deterministic** one and only need to know the **state** and a **regular information** about the counter
- Deciding its existence is PSPACE-hard
- It can be computed in exponential time

# Solvency Games

- Solvency games  $\subset$  OC-MDP with **one controlled** state
- The following questions related to **non-selective** termination are decidable in polynomial time:
  - ” $\exists$  a strategy for  $\mathcal{P}(\{\text{bankrupt}\})$  (i.e. termination)
  - = 0?
  - > 0?
  - < 1?
  - = 1?

## Proof Idea for Case $< 1$

When  $\exists$  a strategy for  $\mathcal{P}(\{\text{bankrupt}\}) < 1$ ?

Easy part – sufficient conditions:

- If  $\exists$  a strategy for  $\mathcal{P}(\{\text{bankrupt}\}) = 0$
- If one of the distributions has positive expected counter change

Hard part is showing they are necessary

## Proof Idea for Case $< 1$

When  $\exists$  a strategy for  $\mathcal{P}(\{\text{bankrupt}\}) < 1$ ?

Easy part – sufficient conditions:

- If  $\exists$  a strategy for  $\mathcal{P}(\{\text{bankrupt}\}) = 0$
- If one of the distributions has positive expected counter change

Hard part is showing they are necessary

# Future Work

- Minimizing questions
- Games
- Refined analysis of the complexity jump
  - Selective Termination: EXPTIME or PSPACE?
  - 1-selective Termination?
- Quantitative case
